

The Best network Topology for this toolkit is a LAN. This is due to the fact it can provide a safe testing environment in which the toolkit performs crawling, reconnaissance, vulnerability testing, and reporting. The LAN gives an isolated environment where the toolkit can communicate with intentionally vulnerable applications without accidentally attacking anything I would not have permission to attack. The vulnerable applications can be placed within a docker network to limit the applications ability to communicate with unrelated systems. The Lan also allows the toolkit to perform basic reconnaissance and record information such as the target IP address, and open ports. Therefore, a LAN Topology seems to be the best for the toolkit's needs.
